

Script Idea

I will add a small rating feature on my Find a Spot page. The user types their name, picks a star rating from 1 to 5, and clicks a button. The script saves the name and the rating in variables, does a tiny calculation to update an average rating, and then changes the text on the page to say "Thanks, NAME! You rated this spot X stars." This lets the page react to the user instead of being plain text.

Goals

- Make the page feel interactive and personal with a short message that includes the user's name.
- Do a useful calculation by updating the average rating each time someone rates a spot.
- Show the result right on the page so the user sees the change immediately.
- Keep everything very simple so it is easy to read and maintain.

Task Breakdown

1. User types their name into a text box - stored in the variable `username` (string).
2. User selects a star rating (1–5) - stored in the variable `rating` (number).
3. User clicks the "Rate" button to run the script.
4. The script adds the new rating to `ratingTotal` and increases `ratingCount` by 1.
5. The script calculates the new average using:
$$\text{averageRating} = \text{ratingTotal} / \text{ratingCount}$$
6. The script updates the page text using `innerHTML` to show a message like:
"Thanks, Alex! You rated this spot 5 stars. The current average rating is 4.2."
7. The result appears right away on the page.

Flowchart:
